~~SPECIFICATION~~

SEMICONDUCTOR LASER CHIP

Field of the Invention

The present invention relates to a semiconductor laser chip according to the definition of the species in Claim 1.

Related Technology

Semiconductor lasers are generally known, as proceeds, for example, from the publication by Dr. Richter, Telekom Vision 7/93, referred to and discussed at the end of this document.

The application of such a laser is described in detail in the publication by K. H. Park, "Fabrication and Transmission Experiments of Distributed Feedback Lasers Modules for 2.5 Gb/s Optical Transmission Systems" published in Optical and Quantum Electronics 27 (1995), 547-552. To further enhance capacity, optical carrier frequency technologies, also referred to as wavelength division multiplex systems, are increasingly being used. The output wavelength of the semiconductor lasers used in these systems must be able to be adjusted and corrected within a very narrow range. Manipulated variables used for this purpose include the externally adjusted temperature of the laser carrier, and the laser's pumping power.

At a constant pumping power, an incorrect determination of the temperature of the laser chip leads to deviations in the output wavelengths, particularly when it is necessary to change the pumping power for operational reasons. The reasons for a change in pumping power can be unplanned, such as the effects of ageing on the laser, or also planned, such as changing the laser's output power in response to a change in path attenuation, or subsequent to a reconfiguration in switched networks (routing, equivalent line circuit).

While in telecommunications lasers the emphasis is on a monomode characteristic and a

26149106 520

small line width, as well as a rapid modulability, for purposes such as material processing, it is important that the semiconductor laser have a high power output. In comparison to telecommunications lasers, high-performance lasers are often very long (up to 2 mm). Unavoidable irregularities due to manufacturing, along the active laser zone, lead to local temperature peaks, particularly in operations entailing the highest power outputs. Such irregular temperature distribution results in a diminished output power and, in the extreme case, to irreversible degradation of the laser.

In known methods heretofore, a laser's temperature is only measured at one location, namely at its laser carrier being used as a heat sink. When measuring the temperature, errors can occur due to the heat transfer resistance between the laser chip and the heat sink, and also due to the finite thermal conductivity of the laser chip material; in addition to this such errors are caused by other heat sources produced by the bulk resistances in the pumping current's path. Besides the steady-state temperature measuring errors, large time constants also result, which adversely affect temperature control. In known methods heretofore, irregularities in the temperature characteristic were not recorded at all in the case of high-performance lasers. German Patent DE 19 546 443 and European Patent EP 0 779 526 describe an optical and/or electro-optical connection, and a method for manufacturing such a connection for two optical and/or electro-optical components. Figure 7 of this publication, in particular, shows how a pump-current lead wire is secured in a semiconductor laser, and provides details of the same in the corresponding description. It also describes how a hole can be bored into a laser chip using laser welding light.

Other laser chips or semiconductor laser modules are fundamentally described in German Patent DE 42 32 326 and in German Patent DE 42 32 327.

As ~~already explained~~ <sup>noted above</sup>, it is customary for the temperature of a laser to be measured at only one location, namely at its laser carrier being used as a heat sink.

## Summary of the Invention

a  
a  
An <sup>provide</sup> ~~The~~ object of the present invention is to ~~provide~~ an arrangement of a temperature sensor or of a plurality of temperature sensors, which will enable a more precise and/or locally resolved measurement of the operating temperature, it also being possible to implement a precise temperature adjustment with substantial accuracy and/or local selectivity.

5  
~~The achievement of this objective in accordance with the present invention is characterized in the characterizing part of Claim 1.~~

10  
Further refinements of the present invention or features are characterized in Claims 2 through 15.

a57  
A very high precision, not attainable in known methods heretofore, is achieved by securing one or a plurality of temperature sensors directly onto the laser chip, and in intimate connection with the same, in a welding operation using Nd-YAG laser light or light having similar properties. The fine temperature adjustment is advantageously carried out using Peltier elements, the components of the Peltier elements being applied directly to the laser chip using Nd-YAG laser light. In accordance with the present invention, the wavelength of the laser chip is measured and, when necessary, the wavelength of the laser chip is also adjusted, the telecommunications lasers having one measuring point per active laser zone, and the high-performance lasers having a plurality of measuring points per laser chip along the active laser zone.

15  
20  
25  
~~Other advantages, features, and possible applications of the present invention are revealed in the dependent claims, as well as in the following description, in conjunction with the drawings. The terms and reference numerals included in the appended list of reference numerals are used in the Specification, Patent Claims, in the Abstract, and in the Figures.~~

a  
<sup>present</sup> Brief Description of the Drawings  
The invention shall ~~now~~ be elucidated <sup>96</sup> ~~on the basis of exemplary embodiments. In the~~ drawings, the figures show:

shown, since the intention here is to merely show the arrangement of an encapsulated temperature sensor 1.

Figure 4 depicts such a temperature sensor 1 in a predrilled hole. Shown here, again, is laser chip 4 having wire 8 for supplying pumping current, as well as wires 2 and 3 for supplying measuring current to temperature sensor 1. Also shown, are wires 2 and 3 for supplying measuring current to temperature sensor 1.

To produce the hole for temperature sensor 1 in laser chip 4, laser light radiation can likewise be used, as described in German Patent 19 546 443.

At this point, it should be remarked that the described method for arranging one or a plurality of temperature sensors, as well as the fine temperature adjustment characterized by high precision and/or local selectivity with respect to temperature is easily applicable to laser chips of thermally isotropic material.

The arrangements in accordance with Figures 5a, 5b and 6 enable the temperature dependency of bulk resistor 11 itself to be measured. The resistor is apparent between the two melting points 10, where the two wires 2 and 3 for supplying measuring current are mounted by welding or another method, for example bonding. Also shown are lead wires 2 and 3 for the measuring current and lead wire 8 for the pumping current.

Figure 5b shows an arrangement having symmetrical sensors, individual laser 5 being configured symmetrically between melting points 10 in laser chip 4. Here, bulk resistor 11 is again disposed between the two measuring points 10.

Figure 6 illustrates that bulk resistor 11 is arranged in parallel to the pumping current circuit, here again, heat sink 6 being connected to laser chip 4 by melting points 18 formed during welding. Heat sink 6 is connected by a wire 7 for supplying the pumping current, and

individual laser 5 is likewise connected by a wire 8 for supplying the pumping current. Wire 3 is connected to melting point 10, to be able to supply the necessary measuring current.

The need is eliminated here for second melting point 10 for wire 2; instead, wire 7 or wire 8 can be jointly used.

Measuring the temperature of individual lasers 5 having bulk-resistance sensors is illustrated in Figure 7. The individual bulk resistors 11 are disposed between melting points 10 of individual lasers 5, which are located on or in a laser chip 4. This demonstrates that when a plurality of individual lasers 5 are configured on one laser chip 4, the temperature of each individual laser 5 can be measured. As a result, it is possible to adjust the output wavelengths of these individual lasers 5 during operation, by way of their pumping currents, without explicitly measuring their wavelength.

A similar technology (Figure 8) makes it possible, when working with high-performance lasers, to measure the temperature distribution along an active-laser zone of an individual laser 5 on or in laser chip 4.

Particular advantages are derived when temperature sensor 1 is a thermoelement. It is then not only possible to secure a previously fabricated thermoelement using laser-light welding, directly onto the measuring object, in close thermal contact with the same, as already described, but it is also possible, in one work step, to join the two individual wires required for the thermoelement, using laser-light welding, to form one thermoelement, and to secure it to the measuring object.

As is evident in Figure 9 from the arrangement of a thermoelement on a laser chip 4, each thermoelement, shown here as measuring point 12, now has one measuring lead wire 2 and one measuring lead wire 3, each of different material.

Before joining wires 2 and 3 on laser chip 4, it is particularly advantageous to vapor-deposit a contact surface 21 on semiconductor laser 4, or to apply it in some other suitable way, this surface 21 either being made of the material of wire 2 or of the material of wire 3 (Figure 9).

5

At the second place where wires 2 and 3 are united, a second thermoelement 13 is formed. At point 14, a voltage that is dependent upon the temperature difference between points 12 and 13 can then be tapped off, in this context, the measuring instrument at point 14 <sup>is</sup> must be surrounded by wires of the same material. Of course, wires 2 and 3 can also be partially or completely designed as printed conductors that are permanently connected to a chip (e.g., to laser chip 4). Temperature-reference point 13 can be on chip 4 itself, on heat sink 6 of semiconductor laser 4, or even on the housing surrounding the entire arrangement, in accordance with Figure 1.

10

Figure 10 shows a design variant that makes do with only one additional wire 3, in which the otherwise necessary wire 2 is the pumping-current lead wire 8, made, for example, of gold or copper. The other wire 3 for thermoelement 12 is made, for example, of Konstantan.

15

A further advantage is derived in a reversed operation by using a thermoelement in accordance with Figure 11 as a Peltier element having a current source 17. Similarly to the measuring arrangement according to Figure 9, here as well, wires 19 and 20 between points 15 and 16 are made of different materials. Depending on the direction of the current from source 17, the heat can be transferred from point 15 to point 16 (main application case: semiconductor laser 4 is cooled) or from point 16 to point 15 (semiconductor laser 4 is additionally heated).

20

25

The Peltier element formed from wires 19 and 20 between points 15 and 16 is fabricated using the same technology as thermoelement pair 2, 3, 12, 13, described in Figure 9.

Using a thermoelement pair functioning as a temperature sensor, in accordance with Figure 9, and a Peltier element 15, 16, 19, 20 operated as a temperature setter, one can precisely adjust the temperature of point 15. To reduce control errors, point 15 should be close to point 12. The controller (not shown) then controls current source 17 as a function of measuring voltage 14 of thermoelement pair 12 and 13, measuring point 13 being an external reference point. In this control, it is beneficial for reference point 13 and thermal reference point 16 (in <sup>an embodiment</sup> ~~the main application case~~, a heat sink) of the Peltier element to have the same temperature. This reference location 13 or 16 can be a point outside of the laser housing <sup>for</sup> (measurement as compared to ambient temperature). However, it is also possible for the reference location to be placed on heat sink 6 of semiconductor laser 4 <sup>for</sup> (measurement of the differential temperature with respect to heat sink 6 of semiconductor laser 4, if indicated, with heat dissipation likewise to heat sink 6 of semiconductor laser 4).

If semiconductor laser 4 is a telecommunications laser, then its output wavelength can be very finely tuned.

For very long lasers 4 (for example, high-performance lasers), it is also possible – as shown in Figure 12 – to configure both thermoelement element pairs 12 and 13, as well as Peltier elements 15 and 16, in a cascade arrangement, to achieve a more homogeneous heat dissipation.

Figure 13 illustrates how the temperature irregularities which limit power output, in particular along the active laser zone 5, can be reduced when working with high-performance lasers, in particular. In a separate controller, each measuring voltage 14 of corresponding measuring point 12 produces its own actuating current 17 for cooling the corresponding heat-dissipation point 15. The dimensional design of the controller is especially simple, when all reference points 13 and all thermal reference points 16 have the same temperature.

When this temperature control that is selective with regard to location is used, it is possible,

for example, to cool especially hot points more intensely than less hot points and, in this manner, achieve a uniform temperature characteristic along the active laser zone 5 of laser chip 4.

- 5 Using the technology described here, one can easily conceive of other refinements or arrangements derived from the particular laser chip and its application area, depending on the requirement.
